Abstract

The major goals in the management of diabetes are to maintain optimum control of high blood glucose level or hyperglycemia. Dietary modification is one of the most recommended treatment modalities for diabetic patients. The use of foods sweetened with sugar alcohols (also known as polyols) such as xylitol, sorbitol, mannitol, maltitol, lactitol, isomalt and erythritol has brought an escalating interest in the recent years since some sugar alcohols do not rise plasma glucose, as they are partially digested and metabolised. Diet composition and adequacy may be altered by replacing carbohydrates with sugar alcohols. It has been established that these polyols are appropriate sugar substitutes for a healthy lifestyle and diabetic foods. The present review focuses on the evidence supporting the use of sugar alcohols in the management of diabetes, by evaluating their physical and chemical properties, metabolism, absorption, glycemic and insulinemic responses. Although documentation on the glycaemic and insulinemic response of polyols is evident that these compounds have beneficial effects on the better management of hyperglycemia, the possible side effects associated with their normal or higher dosages warned their use according to the relevant Food & Drug Administration guidelines. For the same reason, future studies should also focus on the possible toxicity and side effects associated with the consumption of sugar alcohols in order to define their safety.

Keywords: Diabetes, Glycemic index, Insulinemic index, Sugar alcohols, Sweeteners

1. Introduction

The global prevalence of diabetes is increasing progressively, with an estimated 463 million people living with diabetes and a projection of 700 million by 2045, the vast majority of whom have type 2 diabetes (T2D) [1]. Epidemic of diabetes has astounding healthcare expenditure and significant impacts in the quality of life [2]. In 2019, the global diabetes-related healthcare expenditure reached an estimated 760 billion USD, with a 14.5% increase from 2017 [1].

Diabetes is a multifactorial disease and one of its most prominent association is the consumption of excess refined sugar or sugar containing foods and food products [3,4]. Therefore, the World Health Organization issued nutritional guidelines not only

to reduce the consumption of added sugars but also to reduce the daily energy intake from refined sugar [5]. This has led to the identification of modifiable diets and lifestyle factors for the prevention and better management of diabetes [6,7]. A growing interest in products sweetened with sugar alcohols in the market has transpired, targeted towards people with diabetes [8,9]. Studies have suggested that sugar alcohols have the ability to alter the nutritional adequacy of a diet since they have lower energy values due to the way they are metabolized [10]. Therefore, these sugar substitutes are useful in the maintenance of a nutritionally balanced diet for diabetic individuals [11]. Considering all above, the present review was designed to analyse the beneficial effects, mechanisms of actions and possible side effects of different widely used sugar alcohols for the better and safer management of hyperglycemia and diabetes.

2. Sugar alcohols

Sugar alcohols (polyols) are chemically defined as saccharide derivatives in which a ketone or aldehyde group is replaced by a hydroxyl group [9,12]. They are mostly known as caloric/nutritive sweeteners that are white and water-soluble solids which are naturally present in small amounts in some fruits and vegetables and are commercially produced by hydrogenation reaction [8,13,14]. Sugar alcohols are extensively used in sugar-free foods and food products such as gum, fruit spread, candy, baked goods and ice cream [15]. They are used as sugar substitutes in diabetic food formulations to reduce water activity in 'intermediate moisture foods'; improvement of dehydrated foods; as softeners; and as crystallization inhibitors [16]. Some sugar alcohols are also widely used in oral and dental care products due to their proven and relevant beneficial effects [17,18].

2.1. Classification of sugar alcohols

Sugar alcohols (Fig. 1) are classified into three groups according to the number of saccharide units present in the molecule as follows: (i) Mono-saccharide-derived sugar alcohols: for example xylitol, sorbitol and mannitol. These mono-saccharides are derived from xylose, glucose and mannose respectively; (ii) Disaccharide-derived sugar alcohols: this includes lactitol and maltitol which are derived by the hydrogenation of lactose and maltose, respectively. (iii) Polysaccharide-derived sugar alcohols mixture: this includes Iso-malt which is a 1:1 mixture of α -D-glucopyranosyl-[1-6]-D-sorbitol (GPS) and α -D-glucopyranosyl-[1-6]-D-mannitol (GPM) [8,9,15].

2.1.1. Xylitol

Xylitol is a five-carbon crystalline substance occurring naturally in small amounts in many plants, micro-organisms and animal tissues [19,20]. It is produced in humans as part of the hepatic metabolism of carbohydrates at levels of approximately 5–15 g per day [21]. It is also commercially produced by the hydrogenation of xylose using a nickel-catalyzed reaction process [22]. The molecule contains a tridentate ligand ($\text{H}-\text{C}-\text{OH}$)₃ which reacts with numerous polyvalent cations and oxyacids [13]. Xylitol is roughly as sweet as sucrose but with moderately lower caloric value of (2.4 kcal/g) compared to sucrose (4 kcal/g), hence it is widely used in foods and pharmaceutical products [20].

2.1.2. Sorbitol

Sorbitol is a six-carbon alditol also known as D-glucitol. It is naturally present in fruits (peaches, apples, cherries, apricots, nectarines and pears) and some vegetables [23,24]. It is produced from glucose by catalytic hydrogenation with hydrogen gas and nickel catalyst at high temperatures [25,26]. In alkaline conditions it is produced by electrochemical reduction of dextrose [23]. Sorbitol has sweetness of about 60% of sucrose, with fewer calories [9,27]. It also characterizes with a 20-fold higher solubility in water than mannitol [28,29]. Sorbitol has non-cariogenic properties therefore it is used for nutritional purposes in products designated for diabetic people [30].

2.1.3. Mannitol

Mannitol is six-carbon polyol, an optical isomer of sorbitol which is used as a reserve carbohydrate by some fungi, bacteria and seaweeds [31,32]. It is also naturally found in high amounts in olives, carrots, figs, pineapples, sweet potatoes and larches [29,33–35]. Industrial production of mannitol is based on the catalytic hydrogenation of glucose/fructose derived from invert starch or sugar at high temperatures and pressure [33,36]. It has a caloric value of 1.6 kcal/g which is 50% sweet as compared to table sugar, with a desirable cooling effect that is efficient in masking bitter tastes [37]. This sugar alcohol is non-hygroscopic [35], which is used as a bulking agent in sugar free coatings and a dusting powder for chewing gum [9]. Mannitol is not metabolized by humans therefore it doesn't induce hyperglycemia with no insulinemic and glycemic indexes [38].

2.1.4. Maltitol

Maltitol is a disaccharide polyol (4-O- α -D-glucopyranosyl-D-glucitol), formed from the hydrogenation of maltose to produce an α -1,4 glucose-sorbitol linked polyol [9,39,40]. It is a crystalline powder that acts as a bulking agent, a stabilizer, an emulsifier, thickener and sweetener [9]. Maltitol properties such as sweetness and taste resemble that of sucrose [34]. Maltitol is a non-cariogenic agent with applications in many sugar-free foods, as well as numerous reduced-calorie and reduce-fat foods [26,40].

2.1.5. Lactitol

Lactitol is disaccharide sugar alcohol obtained from the hydrogenation of lactose using nickel as a catalyst. Its production is composed of galactose and

sorbitol [41–43]. Lactitol is an odourless white crystalline powder with a sweetness that is 30–40% of sucrose [15,41]. It has an anhydrous form which is applicable in case of moisture-sensitive products. It is used as an emulsifier, thickener and sweetener [9].

2.1.6. Isomalt

Isomalt is a mixture of two isomeric disaccharide alcohols: gluco-sorbitol (α -D-gluco-pyranosyl-1-6-

Sorbitol) and gluco-mannitol (α -D-gluco-pyranosyl-1-6-mannitol) [25]. It is produced from sucrose in a two-step process, which makes isomalt chemically and enzymatically more stable than sucrose [44,45]. Isomalt on average has 45–65% of the sweetness of sucrose. It has synergistic effects when combined with other sugar alcohols or with high-intensity sweeteners, it is also anti-cariogenic and does not increase blood glucose or insulin levels [9,30]. This

Fig. 1. Chemical structure of commonly used sugar alcohols.

polyol is partially digested in the intestines, only supplying half the caloric value of sucrose [39,45].

2.1.7. Erythritol

Erythritol is a four-carbon polyol, that occurs naturally and widely distributed in nature. It occurs as a storage or metabolite compound in fungi and seaweeds, and as a constituent of numerous fruits such as pears, melons and grapes [12,46]. It is also commercially produced using fermentation in processed vegetables, fermented foods and drinks [12]. It is a symmetrical molecule, therefore existing in one form, the meso form [13]. It forms anhydrous crystals with approximately 60–80% sweetness that of sucrose, with no caloric effect and good digestibility without impacting blood glucose and insulin levels [47,48]. Its other general features include high stability in acidic and alkaline environments, and high stability against heat [46].

2.2. Physical and chemical properties

The probability of a sugar alcohol to be used as a sweetener depends on its properties which include physical, chemical, processing and sensory (Table 1) [16]. These compounds have numerous common properties that are important in selecting the most suitable polyol for a food application, these include:

- **Sweetness:** Sweetness is an important property of any sugar alcohol or sugar alternative. The sweetness of sugar alcohols is measured relatively to the sweetness of sucrose or table sugar. The sweetness of sugar alcohols varies from half as sweet to equal of that of sucrose (Table 2) [9,39].
- **Cooling Effect (Heat of solution):** Each sugar alcohol is characterized by negative heat of solution which is the energy requiring process to dissolve the crystals. Some polyols such as isomalt have a noticeable high heat in solution followed by a cooling effect in the mouth. Cooling effect together with sweetness are midst the most important properties of polyols in their use in pharmaceutical products with soothing effects, i.e., breath mints, cough drops and lozenges [13,40,49].
- **Solubility:** The solubility of sugars and polyols in water is greatly affected by the extent of temperature. The solubility of the compounds increases with temperature. Some polyols such as xylitol are highly soluble in water. Others like mannitol are slightly but it does not confine their use in food applications [16].
- **Hygroscopicity:** Hygroscopicity is the tendency for materials to take up moisture from their surroundings or atmosphere. The hygroscopicity of food products has very serious significance during the production and storage of the food, and it may affect how the ingredient itself is stored. Polyols that are highly water-soluble also tend to be very hygroscopic. This behaviour may assist in adding and retaining moisture in food products [16,25].
- **Molecular weight:** The molecular weight of polyols is important when replacing sugars with polyols, to ensure the colligative properties remain unaffected. It can impact the texture, viscosity, osmotic pressure, freezing properties and crystallization [40].
- **Reducing power:** Sugar alcohols have additional hydrogen atoms which can be deposited on other metabolites to produce chemically reduced products and intermediates of metabolism [19]. Reducing power of different sugar alcohols denote the level of their antioxidant activity [50,51].
- **Hydrophilicity:** Sugar alcohols have a great number of hydroxyl groups making them readily soluble in saliva. Xylitol and erythritol are highly hydrophilic sugar alcohols which are able to compete with water molecules for the hydration layer of biomolecules [19].
- **Absence of a reducing carbonyl group:** This property makes the molecules less reactive chemically than the corresponding ketoses and aldoses. Therefore, some polyols avoid these chemical reactions that make many dietary hexose-based sugars acidogenic and cariogenic in human dental plaque [52].

Table 1. Chemical and physical characteristics of Sugar Alcohols [Adapted from Refs. [9,37,49].

Sugar alcohol	Molecular weight	Melting point (°C)	Heat of solution	Viscosity at 25 °C	Hygroscopicity
Xylitol	152.15	94	−36	Very low	Medium
Sorbitol	182.17	97	−26	Medium	High
Mannitol	182.172	165	−29	Low	Low
Maltitol	344.313	150	−19	Medium	Medium
Lactitol	344.313	94	−14	Very low	Very low
Isomalt	688.62	167	−9	High	Low
Erythritol	122.12	121	−43	Very low	Very low

Table 2. Relative sweetness of sugar alcohols compared to sucrose [Adapted from Ref. [9]].

Sugar alcohol	Sweetness (Sucrose = 1)
Xylitol	1.0
Sorbitol	0.5–0.7
Mannitol	0.5–0.7
Maltitol	0.9
Lactitol	0.3–0.4
Isomalt	0.45–0.65
Erythritol	0.6–0.8

- **Free radical scavenging:** Because of their polyol nature, some sugar alcohols, such as D-mannitol, xylitol and erythritol, have been investigated as potential sources of free radical scavenging activity in biological systems [13,53].
- **Complexation:** Sugar alcohols can form complex compounds (chelate-like structures), due to their polyoxy structure. Complexes with calcium iron are important in view of tooth mineralization. These complexes are not strong enough to play a part in tooth demineralization. However, the presence of sugar alcohols in the mouth is believed to enable remineralization of caries lesions [19].

2.3. Physiological aspects

2.3.1. Digestion, absorption and metabolism of sugar alcohols

Disaccharide-derived and polysaccharide-derived sugar alcohols are converted into their monosaccharide components after ingestion. Most of these monosaccharides are thereafter absorbed through passive diffusion in the small intestine [54]. Most of the sugar alcohols are partially absorbed from the human small intestine, approximately from 0% for lactitol to nearly 80% for sorbitol [8]. The unabsorbed sugar alcohols are metabolized indirectly through fermentative degradation by colonic bacteria producing short chain fatty acids [39,52]. These are absorbed, providing energy to the body. It has been shown that sugar alcohols are incompletely metabolised in humans, as they have been recovered in urine [8]. The partial absorption and incomplete metabolism of sugar alcohols suggests that they provide lesser amounts of energy compared to sucrose [37,55].

2.3.2. Caloric value

Polyols are known to have lower nutritional values compared to sucrose (Table 3). The energy provided by each sugar alcohol differs because of their digestibility, absorption and metabolism [9,37].

Table 3. Caloric values of sugar alcohols [Adapted from Refs. [35,47]].

Sugar alcohols	Caloric value (kcal/g)			
	Europe	Japan	America	Mean caloric value
Xylitol	2.4	3	2.4	2.6
Sorbitol	2.4	3	2.6	2.7
Mannitol	2.4	2	1.6	2
Maltitol	2.4	2	2.1	2.1
Lactitol	2.4	2	2	2.1
Isomalt	2.4	2	2	2.1
Erythritol	0	0	0	0
Sucrose	4	4	4	4

The energy content varies according to different legislations (Table 3). In Europe, the caloric value of sugar alcohols is set at 2.4 kcal/g except for erythritol which has a value set at 0 kcal/g since it cannot be metabolized [37,49]. However, the legislations in Japan and America set the caloric value of polyols within the range of 0–3 kcal/g [9,39,49]. The minute caloric value of polyols proposes in helping consumers to reduce their energy intake and to lose weight [39]. Details caloric values of different sugar alcohols as specified in different countries are presented in Table 3.

2.3.3. Blood glucose and insulin response

Polyols are considered to elicit low glycaemic and insulinemic responses due to the incomplete absorption into the blood stream from the small intestine (Table 4) [13,53]. They are also associated with lipogenesis inhibition as well as lower insulin production. These properties make polyols popular sweeteners among diabetics and people on low carbohydrate diets [9,56]. The detail effects of sugar alcohols on diabetics are presented in Table 5.

2.4. Studies on antidiabetic properties of sugar alcohols

2.4.1. Xylitol

The consumption of xylitol is accepted for diabetes to help in the management of hyperglycemia as its metabolism is in dependant of insulin [9,49]. Numerous studies have been undertaken to

Table 4. Glycaemic and insulinemic indexes of Sugar Alcohols [Adapted from Refs. [38,49,53]].

Sugar alcohol	Glycaemic index	Insulinemic index
Xylitol	13	11
Sorbitol	9	11
Mannitol	0	0
Maltitol	35	27
Lactitol	6	4
Isomalt	9	6
Erythritol	0	2
Sucrose	69	48

Table 5. Effects of sugar alcohols on diabetic parameters.

Disease model	Treatment	Duration	Mechanisms of action	References
Type 2 diabetic rats	10% xylitol solution (Ad libitum)	4 weeks	<ul style="list-style-type: none"> • Diabetic parameters including pancreatic morphology and serum lipids improved 	[58]
Non-diabetic and type 2 diabetic rats	164.31–2628.99 mM xylitol in vitro. 657.25–2628.99 mM xylitol ex vivo. Xylitol (1 g/kg bw)	2 h Single oral dose	<ul style="list-style-type: none"> • Reduction of blood glucose and serum fructosamine • Inhibited α-amylase and α-glucosidase activities and jejunal glucose absorption. • Improved muscle glucose uptake • Delayed gastric emptying • Reduced blood glucose level 	[59]
Non-obese healthy men	25 g of xylitol	Single oral dose	<ul style="list-style-type: none"> • Lower plasma glucose and insulin response compared to glucose 	[65]
Non-diabetic human subjects	25 or 50 g of sorbitol	Single oral dose	<ul style="list-style-type: none"> • Did not significantly elevate glucose levels 	[70]
No-diabetic and type 2 diabetic rats	2.5–20% sorbitol ex vivo. Sorbitol (0.4 g/kg bw)	2 h Single oral dose	<ul style="list-style-type: none"> • Inhibited jejunal glucose absorption. • Increased muscle glucose uptake • Delayed gastric emptying • Reduced blood glucose level 	[73]
Non-diabetic rats	Diet containing 20% mannitol	8 weeks	<ul style="list-style-type: none"> • Normal glucose metabolism • Lower serum insulin response and cholesterol concentrations 	[74]
Non-diabetic human subjects	50 g of maltitol	Single oral dose	<ul style="list-style-type: none"> • Lower plasma glucose and insulin response compared to sucrose 	[77]
Non-diabetic and type 2 diabetic human subjects	30 or 50 g of maltitol		<ul style="list-style-type: none"> • Lower plasma glucose and insulin response compared to sucrose 	[78]
Non-obese healthy men	25 g of lactitol	Single oral dose	<ul style="list-style-type: none"> • Rise in plasma glucose, insulin and C-peptide concentrations were lower compared to glucose 	[65]
Non-diabetic healthy human subjects	30 g of isomalt (Daily)	4 weeks	<ul style="list-style-type: none"> • Lower postprandial plasma glucose and reduced fructosamine compared to sucrose 	[44]
Non-diabetic and type 2 diabetic rats	2.5–20% erythritol ex vivo. Erythritol (1 g/kg bw)	2 h Single oral dose	<ul style="list-style-type: none"> • Increased muscle glucose uptake • Reduced intestinal glucose absorption and gastric emptying 	[85]
Type 2 diabetic rats	100, 200 or 400 mg of erythritol (Daily)	10 days	<ul style="list-style-type: none"> • Decreased serum glucose levels compared to control • Reduction of thio-barbituric acid reactive substances, creatinine and 5-hydroxymethylfurfural compared to control 	[92]

examine the effects of xylitol on blood glucose and insulin levels for inclusion in diabetic foods. Mushtaq et al. [22] reported the ability of xylitol (extracted from mung bean hulls) as a supplement for three weeks to reduce serum glucose in normal and diabetic rats with a reduction in food intake and weight gain in a dose dependent manner. Therefore, indicating its glycemic control effect [22]. The supplementation of 10% xylitol has demonstrated the ability to improve diabetes associated parameters including reduction in blood glucose and serum fructosamine levels, better glucose tolerance in diabetic rats [57,58]. A study by Chukwuma and Islam [59] examined the mechanisms behind the anti-diabetic effects of xylitol using numerous experimental models. It was reported that increasing concentrations of xylitol dose dependently inhibited α -amylase and α -glucosidase enzymes activity *in vitro*. Secondly, in *ex vivo* condition, xylitol dose-dependently decreased intestinal glucose absorption and increased muscle glucose uptake. Furthermore, a bolus dose of xylitol significantly delayed gastric emptying with increased intestinal transit time in non-diabetic and diabetic rats [59].

The supplementation of xylitol in rats receiving a high-fat diet has been shown to be beneficial in preventing obesity and metabolic abnormalities in a study conducted by Amo et al. [60]. It was observed that xylitol-fed rats compared to high fat diet fed rats had significantly lower visceral fat mass and plasma lipid concentrations, with an increase in lipogenic enzymes, fatty acid oxidation and ChREBP [60]. Xylitol consumption in type 2 diabetic rats has also been implicated in ameliorating oxidative stress, a factor associated with the exacerbation of diabetes [61].

In human studies, it has been observed that oral administration of xylitol causes small increase in blood glucose in healthy and diabetic patients [62–64]. Similarly, plasma insulin concentrations do not upsurge [62] or only moderately increase after the administration of xylitol [64]. Xylitol in comparison to glucose in healthy non-obese men after ingestion had significantly lower increases in plasma glucose and insulin concentrations [65]. These observations confirm that xylitol does not increase blood glucose to a significant extent. It has also been reported that xylitol has a good tolerance at doses ranging from 20 to 70 g/day [66]. A study by Foerster et al. [67] reported the good tolerance of xylitol in diabetic children with type 1. The study was conducted for four weeks with each child receiving 30 g/day of xylitol [67]. The tolerance of xylitol was further observed at a higher

dose of 70 g/day in type 1, type 2 and healthy individuals over a period of six weeks [68]. The data from these investigations present that xylitol can be safely used as a sugar alternative in diabetic foods.

2.4.2. Sorbitol

The use of sorbitol as a sweetening agent in diabetic foods/diets has received substantial attention since its first recommendation for this purpose in 1929 [69]. In 1941 [70], Ellis and Krantz observed that a single dose of 25 or 50 g of sorbitol does not elevate blood glucose levels in normal individuals [70]. They further examined the oral administration of 50 g of sorbitol in mild and moderately severe diabetics reported that sorbitol did not significantly induce postprandial hyperglycemia [71]. A study by Kang et al. [72] investigated the inhibitory activity of sorbitol against rat intestinal α -glucosidase and porcine pancreatic α -amylase *in vitro*. It was reported that sorbitol possesses an inhibitory effect on these carbohydrate digesting enzymes [72]. These observations suggest the anti-hyperglycemic activity of sorbitol. Sorbitol has also shown its apparent glycemic control effects *ex vivo* and *in vivo*. It was reported to inhibit glucose absorption in rat jejuna and increased glucose uptake in rat psoas muscle with or without insulin in a concentration dependant manner, *ex vivo*. In normoglycemic and type 2 diabetic rats, sorbitol delayed gastric emptying, enhanced digesta transit, inhibited intestinal glucose absorption and decreased blood glucose levels. Therefore, it was documented that sorbitol has a potential to be used as an anti-hyperglycemic sweetener in diabetic foods and food products [73].

2.4.3. Mannitol

Mannitol has glycemic and insulinemic indexes of 0, thus it does not induce hyperglycemia which allows it to be consumed by diabetic individuals [33,39]. Mäkinen and Hamalainen [74] studied the effects of feeding high amounts of mannitol on rat metabolism. The animals were fed a diet that contained 20% mannitol for 8 weeks. The animals presented normal glucose metabolism, associated with lower blood glucose levels and higher liver glycogen levels compared to the control animals. The animals also presented lower insulin secretion and lower serum cholesterol concentrations. Therefore, the metabolism of mannitol can be maintained within normal physiological limits [74]. A study by Dillard et al. [75] investigated the toxicity of alloxan in rats in relation to pentane and ethane produced during lipid peroxidation induced by i.p. injection of 20 mg of alloxan/100 g b.w. Animals injected with 100 mg

of mannitol/100 g b.w (i.p) 30 min prior to alloxan were protected from the peroxidative effects of alloxan which was shown by the reduced production of pentane and ethane. The prevention in the formation of thiobarbituric reactants in plasma and liver of the animals additionally presented the protective effect of mannitol. Mannitol further reduced the plasma glucose in the animals after alloxan injection, presenting its hyperglycemic potential [75].

2.4.4. Maltitol

Maltitol is one of the most absorbed and metabolized disaccharide polyols. However, its glucose and insulin response after its consumption is lower as compared to sucrose [9]. A study conducted *in vitro* has shown that maltitol is able to exhibit significant inhibition of α -glucosidase and α -amylase activities [72]. Moreover, maltitol has been reported to inhibit glucose absorption in isolated rat jejunum and increased glucose uptake in isolated rat psoas muscle in the presence of insulin [76]. These observations suggest the use of maltitol for diabetic individuals by reducing carbohydrate digestion, absorption of glucose and postprandial hyperglycemia [72,76].

The available data on human studies suggest that maltitol is a good alternative sweetener to sucrose. A single dose of 50 g maltitol led to significantly lower glucose and insulin responses in healthy young subjects compared to sucrose [77]. A single oral dose of 30 g or 50 g maltitol in type 2 diabetic subjects also exhibited lower glucose and insulin responses compared to sucrose [78,79]. Additionally, a study by Quilez et al. [80] examined the consumption of low-calorie muffins containing maltitol compared to conventional plain muffins in non-diabetic healthy subjects. The subjects fed with maltitol showed improved blood glucose, insulin and lipidemic response in comparison to conventionally fed subjects [80].

2.4.5. Lactitol

The metabolism of lactitol is unique, once consumed it presents a negligible effect on blood glucose levels. It passes undigested to the colon, without being broken down by any enzymatic activity in the intestine. Henceforth, there is no condition for insulin rendering it appropriate for diabetic individuals [9,49]. Natah et al. [65] reported that after the ingestion of 25 g lactitol, the rise in plasma glucose, insulin and C-peptide concentrations were lower compared to ingestion of 25 g glucose in healthy non-obese men. It was suggested that lactitol is a suitable component in the diet for

diabetic patients due to its lower glucose and insulin responses [65].

A study by Shimomura et al. [81] examined the effects of ingesting a 46 g non-sugar chocolate containing polydextrose and lactitol in place of sucrose and lactose on the concentrations of plasma, insulin and triglycerides in healthy non-diabetic subjects. The non-sugar chocolate had minor effects on the elevation of plasma and insulin concentrations compared to the control chocolate after ingestion. The serum triglycerides were slightly elevated in non-sugar chocolate subjects; however, this parameter was gradually increased in the control subjects. Additionally, an animal study also presented reduced response of serum triglyceride to the administration of a fat emulsion containing polydextrose and lactitol. These observations suggested that the non-sugar chocolate may have a less effect on body fat deposition [81].

2.4.6. Isomalt

Over the years the use of isomalt by humans has shown that insulin and blood glucose levels only increase slightly compared to conventional sugar [9,39,82]. The impact of isomalt consumption on physiological and metabolic markers with regards to obesity and diabetes was examined in healthy volunteers. It was reported that consumption of milk chocolate containing 70 g isomalt resulted in lower postprandial plasma glucose compared to chocolate containing sucrose. Volunteers that had consumed isomalt presented a reduction in glycation products such as fructosamine and glycated haemoglobin (HbA1c) which are associated in delaying the manifestation of diabetes lesions. Therefore, suggesting its possible benefits for diabetes [44]. Holub et al. [83] examined the effect of isomalt in patients with T2D for 12 weeks with 30 g of isomalt alternatively to higher glycemic carbohydrates. The diet was tolerated with significant reductions in fructosamine, glycated haemoglobin, fasting blood glucose, insulin, C-peptide, proinsulin, insulin resistance (HOMA-IR) and oxidized LDL. It was established that 30 g isomalt improved the metabolic control of the diabetic patients significantly [83].

2.4.7. Erythritol

Erythritol has been reported to contribute no calories and being well tolerated (good digestibility) without any impact on blood glucose and insulin levels. Thus making it appropriate for use in diabetic foods and diets [46,84]. Chukwuma et al. [85] examined the effect of erythritol on glucose absorption and glucose uptake in various

experimental models. *Ex vivo*, the effect of erythritol was determined by monitoring the glucose concentration change in an incubation containing either isolated rat jejunum or psoas muscle at different concentrations (2.5–20%) of erythritol. Erythritol presented an increase in glucose uptake in isolated psoas muscle with or without insulin in a dose dependant manner. Insulin significantly improved the effect of erythritol on muscle glucose uptake. *In vivo*, the effect of an oral dose of erythritol (with phenol red as recovery marker) in normal and T2D rat model was examined on intestinal glucose absorption, gastric emptying and postprandial blood glucose. Erythritol significantly reduced glucose absorption in the first quartile of the small intestine of normal and diabetic animals. It also reduced gastric emptying in diabetic animals, thus preventing a rise in blood glucose [85].

In a previous study, the supplementation of erythritol in doses of 100, 200, or 400 mg (kg body weight)^{−1} day^{−1} for ten days in diabetic rats induced with streptozotocin, decreased serum glucose levels significantly with a dose dependant reduction of thio-barbituric acid reactive substances, creatinine and 5-hydroxymethylfurfural in liver, kidney and serum. The study implied that erythritol affects glucose metabolism and reduces lipid peroxidation thus refining oxidative damage involved in the pathogenesis of diabetes [86].

In human studies, Wölnerhanssen et al. [87] investigated the effect of a single bolus dose of 75 g of erythritol dissolved in 300 mL water given to lean and obese non-diabetic subjects. The acute ingestion of erythritol led to stimulation of gut hormone release (CCK and GLP-1), with significant delayed gastric emptying. Additionally, insulin and plasma glucose concentrations were not affected [87]. Overduin et al. [88] examined the effect of isovolumic meal with partial replacement of sucrose by erythritol in lean and obese subjects. They found lower glucose and insulin levels after erythritol than after sucrose meals. There was no difference in the secretion of GLP-1/PPY levels, subsequent energy intake and sucrose preference between a control meal with sucrose and isovolumic erythritol meals. It was concluded that the satiating effect of the different preloads were comparable [88].

2.5. Safety of sugar alcohols

The Food and Drug Administration (FDA) classifies some polyols as approved food additives. These include erythritol, hydrogenated starch hydrolysates, isomalt, lactitol, maltitol, mannitol, sorbitol, and xylitol [9,89,90]. Although, the excessive

consumption of polyols causes gastrointestinal symptoms and laxative effects in both humans and animals [13,89,91,92], acceptable daily intake of polyols has been recommended by the Joint FAO/WHO Expert Committee of Food Additives (JECFA) after extensive toxicological testing [25]. However, in 2017 the European Food Safety Authority called for the safety of polyols used as food additives to be re-evaluated. This re-evaluation will be finalized by the end of 2020 [93].

2.5.1. Xylitol

Xylitol has been reported to possess numerous positive effects, however, its excessive consumption can affect human health negatively [94]. It has a laxative effect, although the tolerance varies from person to person [13]. It can result in temporary gastrointestinal side effects, such as bloating, flatulence, and diarrhea [66,95]. Akerblom et al. [96] reported that four out of thirteen children experienced transient diarrhea from the consumption of more than 65 g/day xylitol [96]. A study by Wölnerhanssen et al. [87] reported that 50 g xylitol bolus in 200 mL water led to bloating and diarrhea in 70% of all subjects. A review by Mäkinen [66], suggests that the highest safe doses of xylitol ranges from 20 to 70 g/day. The slow absorption of xylitol from the gut, and the resulting osmotic imbalance, are considered to be the cause of these gastrointestinal side effects, which can be reversed on termination or reduction of the amounts consumed [25].

2.5.2. Sorbitol

Sorbitol is generally regarded as safe for use as an additive for human food [25]. However, the excessive ingestion of sorbitol may lead to flatulence, abdominal pain and mild to severe diarrhea [13]. The consumption of 20 g (0.7 oz)/day of sorbitol as sugar-free gum causes diarrhea resulting to unintentional loss of weight or requiring hospitalization [97]. The addition of sorbitol to sodium polystyrene sulfonate (sps, used in treatment of hyperkalemia) can cause gastrointestinal tract complications, including perforated colonic ulcers, bleeding, ischemic colitis and colonic necrosis [13]. The risk factors for damage induced sorbitol in humans include immune suppression, hypovolemia, peripheral vascular disease, postoperative setting and hypotension [98].

2.5.3. Mannitol

Mannitol is the least well tolerated sugar alcohol with a daily laxative threshold amounting to 20 g [14,36]. The accumulation of maltitol may lead to amplified levels of extracellular fluid which may

cause asymptomatic heart failure. The intravenous administration of 20% mannitol can cause electrolyte abnormalities such as hypocalcemia, hypokalemia and hyponatremia [99,100]. Hypokalemia may cause nausea, headache, convulsions, vomiting and even coma [100]. It has been reported that an excessive dose of intravenous mannitol can cause acute and persistent nephrotic syndrome [101]. Mannitol worsens cerebral edema when it leaches across the blood–brain barrier, it draws water into instead of out of the brain. This occurs especially in patients with intracranial haemorrhage and children with cerebral hyperemia upon mannitol administration [100]. Mannitol has been suggested to be safe in the elderly and adults at doses ranging from 20 to 100 g/day, depending on body weight and health status [95].

2.5.4. Maltitol

Maltitol is a low digestible carbohydrate, it is not fully metabolized in the small intestine. Therefore, there is concern of over excessive consumption resulting in laxative side effects [102]. Data from literature suggests that 30 g of maltitol can be ingested as an individual portion in most adults without any laxative effect. The body weight is an important factor regarding the laxative effect of maltitol, a maximum single dose of 0.3 g/kg b.w in adults has been reported to have no laxative effect [103]. Koutsou et al. [104] observed that 30 g maltitol in milk chocolate does not increase digestive discomfort in adults, except for mild flatulence [104]. Maltitol at a higher dose of 40 g increases colic, borborygmi and flatus, however it does not induce diarrhea [104,105]. Thabuis et al. [106] examined the digestive tolerance of 15 g/day maltitol in children. The study indicated that maltitol was relatively well tolerated with minor abdominal discomfort [106]. The regular consumption of maltitol is not associated with severe digestive discomfort, diarrhea occurs at much higher doses than those currently consumed [107].

2.5.5. Lactitol

Lactitol consumption like most sugar alcohols causes cramping, diarrhea and flatulence in some people, this result due to the deficiency of the enzyme beta-galactosidase in the upper gastrointestinal tract [97]. Lee & Storey [108] found that consumption of chocolate containing 20 g of lactitol resulted in bloating, flatulence, colic and borborygmi compared to chocolate containing sucrose in healthy adults. It was also associated with causing diarrhea in the subjects [108]. The laxative effects of lactitol depends on age, person's diet, general gut

health and the mode and frequency of digestion [9,42].

2.5.6. Isomalt

The ingestion of isomalt in excess is associated with increased colonic fermentation confirming its probability to cause abdominal bloating, flatulence, stomach ache and rumbling noises [109–111]. Subjects ingesting 100 g milk chocolate containing 40 g isomalt reported the incidence of colic, flatulence, borborygms, loose stools, motion frequency and mild laxation. However the reduction in isomalt to 30 g increased tolerance with evidence of mild gastrointestinal side effects [104]. The laxative effect of this sugar alcohol depends on the form in which it is ingested, individual sensitivity, the moment, and frequency of consumption [25].

2.5.7. Erythritol

The safety evaluation of erythritol has been thoroughly reviewed, these studies have demonstrated that it is well tolerated [84,112,113]. The digestive tolerance study by Tetzloff et al. [114], reported that 1 g/kg b.w erythritol consumed over one week can be well tolerated by humans. Storey et al. [115] examined gastrointestinal tolerance after a single oral bolus dose of either 20 g, 35 g or 50 g of erythritol in seven healthy young adults. Twenty grams and 35 g erythritol did not trigger any gastrointestinal symptoms, while the highest dose (50 g) led to an increased number of subjects reporting nausea and borborygmi [115]. Erythritol compared to other sugar alcohols has a lower probability to cause laxative effects. This high laxative threshold enables its use in products such as diet beverages [25]. The consumption of this sugar alcohol from natural sources has been estimated at the level of 106 mg/person/day in Japan, whereas in USA at 25 mg/person/day [116].

3. Conclusion

Over the years there has been an escalating interest in the use of polyols as alternative sugars. These compounds look and taste like sugar but are excellent substitutes due to various physical, chemical and biological properties. Numerous studies have shown that polyols have a number of health benefits. Documentation on the glycaemic and insulinemic response of polyols is evident that these compounds have a negligible effect on to postprandial glycemia and insulinemia. Therefore, they are suitable for use by people with diabetes or anyone who wants to live a healthy lifestyle. Continued investigation in diabetic food products is

still required to ascertain the undiscovered potential of sugar alcohols as alternative sugar substitutes. However, despite these antidiabetic studies there are some possible side effects associated with its usage at normal or higher doses due to the different tolerance ability of different individuals. Thus, future studies should also focus on the possible side effects of different sugar alcohols in humans in order to define their safety.

Conflict of interest

The authors declare no conflict of interests.
